

## Investigating a switch from daily HIV medications

If you are living with HIV and have been undergoing treatment for at least 6 months, you might be able to participate in a clinical research study.

The SOLAR study is being conducted to learn if a combination of two investigational\* medications, taken every 2 months, can keep the amount of HIV virus in your body at low levels compared to a combination of three HIV medications, taken daily as a single tablet.

Eligible study participants will be assigned at random (like flipping a coin) to one of two options:

- Continue current HIV medications (about 33% of participants)
- Switch to the investigational medications (about 67% of participants)

Study participation will last 1 year, with the potential to enter an extension phase of the study after that. In the extension phase, all participants will receive the investigational medications.

Investigational medications and study-related tests and procedures will be provided at no cost.

You may be able to participate in the study if you:

- Are at least 18 years old (Minimum age may be higher in some countries.)
- Have been diagnosed with HIV that is controlled (suppressed) by your current HIV medications
- Have been on the same HIV medications and doses for at least 6 months (approximately)

There are other requirements that the study doctor will discuss with you.
